```
confint.lad Confidence intervals from lad models
```

## Description

Computes confidence intervals for one or more parameters in a fitted model corresponding to a lad object.

## Usage

\#\# S3 method for class 'lad'
confint(object, parm, level $=0.95, \ldots$ )

## Arguments

object a fitted model object.
parm a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
level the confidence level required.
$\ldots \quad$ additional argument(s) for methods.

## Details

confint is a generic function. Confidence intervals associated to lad objects are asymptotic, and needs suitable coef and vcov methods to be available.

## Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - ( 1 -level)/2 in \% (by default $2.5 \%$ and $97.5 \%$ ).

## See Also

confint.glm and confint.nls in package MASS.

## Examples

```
fm <- lad(stack.loss ~ ., data = stackloss, method = "BR")
confint(fm) # based on asymptotic normality
```

11fit Minimum absolute residual (L1) regression

## Description

Performs an L1 regression on a matrix of explanatory variables and a vector of responses.

## Usage

l1fit(x, y, intercept $=$ TRUE, tolerance $=1 \mathrm{e}-07$, print.it $=$ TRUE)

## Arguments

x
vector or matrix of explanatory variables. Each row corresponds to an observation and each column to a variable. The number of rows of $x$ should equal the number of data values in $y$, and there should be fewer columns than rows. Missing values are not allowed.
y numeric vector containing the response. Missing values are not allowed.
intercept logical flag. If TRUE, an intercept term is included in the regression model.
tolerance numerical value used to test for singularity in the regression.
print.it logical flag. If TRUE, then warnings about non-unique solutions and rank deficiency are given.

## Details

The Barrodale-Roberts algorithm, which is a specialized linear programming algorithm, is used.

## Value

list defining the regression (compare with function lsfit).
coefficients vector of coefficients.
residuals residuals from the fit.
message vector of one or two character strings stating whether a non-unique solution is possible, or if the $x$ matrix was found to be rank deficient.

## Examples

l1fit(stack.x, stack.loss)

## Least absolute deviations regression

## Description

This function is used to fit linear models considering Laplace errors.

## Usage

lad(formula, data, subset, na.action, method $=$ "BR", tol $=1 \mathrm{e}-7$, maxiter $=200$, model $=$ TRUE, $x=$ FALSE, $y=$ FALSE, contrasts $=$ NULL)

## Arguments

| formula | an object of class "formula": a symbolic description of the model to be fitted. |
| :--- | :--- |
| data | an optional data frame containing the variables in the model. If not found in <br> data, the variables are taken from environment (formula), typically the envi- <br> ronment from which lad is called. |
| subset | an optional expression indicating the subset of the rows of data that should be <br> used in the fit. <br> a function that indicates what should happen when the data contain NAs. |
| na.action | character string specifying the fitting method to be used; the options are "BR" <br> Bethod <br> using IRLS. |
| tol | the relative tolerance for the iterative algorithm. Default is tol = 1e-7. |
| maxiter | The maximum number of iterations for the EM method. Default to 200. |
| model, $x, y$ | logicals. If TRUE the corresponding components of the fit (the model frame, the <br> model matrix, the response) are returned. |
| contrasts | an optional list. See the contrasts.arg of model.matrix. default. |

## Value

An object of class lad representing the linear model fit. Generic function print, show the results of the fit.
The functions print and summary are used to obtain and print a summary of the results. The generic accessor functions coefficients, fitted.values and residuals extract various useful features of the value returned by lad.

## Author(s)

The design was inspired by the R function 1 m .

## Examples

```
fm <- lad(stack.loss ~ ., data = stackloss, method = "BR")
summary(fm)
```

lad.fit

Fitter functions for least absolute deviation (LAD) regression

## Description

This function is a switcher among various numerical fitting functions (lad.fit.BR, and lad.fit.EM). The argument method does the switching: "BR" for lad.fit.BR, etc. This should usually not be used directly unless by experienced users.

## Usage

lad.fit(x, y, method = "BR", tol = 1e-7, maxiter = 200)

## Arguments

| x | design matrix of dimension $n \times p$. |
| :--- | :--- |
| y | vector of observations of length $n$. |
| method | currently, methods "BR" (default), and "EM" are supported. |
| tol | the relative tolerance for the iterative algorithm. Default is tol $=1 \mathrm{e}-7$. |
| maxiter | The maximum number of iterations for the EM method. Default to 200. |

## Value

a list with components:

| coefficients | a named vector of coefficients. |
| :--- | :--- |
| scale | final scale estimate of the random error. |
| residuals | the residuals, that is response minus fitted values. |
| fitted.values | the fitted values. |
| SAD | the sum of absolute deviations. |
| weights | estimated EM weights. |
| basic | basic observations, that is observations with zero residuals. |
| logLik | the log-likelihood at convergence. |

## See Also

lad.fit. BR, lad.fit.EM.

## Examples

```
x <- cbind(1, stack.x)
fm <- lad.fit(x, stack.loss, method = "BR")
fm
```

lad.fit-methods Fit a least absolute deviation (LAD) regression model

## Description

Fits a linear model using LAD methods, returning the bare minimum computations.

## Usage

lad.fit. $\operatorname{BR}(x, y, t o l=1 e-7)$
lad.fit.EM(x, y, tol = 1e-7, maxiter = 200)

## Arguments

$\mathrm{x}, \mathrm{y} \quad$ numeric vectors or matrices for the predictors and the response in a linear model. Typically, but not necessarily, $x$ will be constructed by one of the fitting functions.
tol the relative tolerance for the iterative algorithm. Default is tol $=1 \mathrm{e}-7$.
maxiter The maximum number of iterations for the EM method. Default to 200.

## Value

The bare bones of a lad object: the coefficients, residuals, fitted values, and some information used by summary.lad.

## See Also

lad, lad.fit, lm

## Examples

```
x <- cbind(1, stack.x)
z <- lad.fit.BR(x, stack.loss)
z
```

## Description

Density, distribution function, quantile function and random generation for the Laplace distribution with location parameter location and scale parameter scale.

## Usage

dlaplace $(x$, location $=0$, scale $=1, \log =$ FALSE $)$
plaplace (q, location $=0$, scale $=1$, lower.tail $=$ TRUE, log. $p=$ FALSE)
qlaplace ( p, location $=0$, scale $=1$, lower.tail $=$ TRUE, log. $\mathrm{p}=$ FALSE)
rlaplace(n, location $=0$, scale $=1$ )

## Arguments

$x, q \quad$ vector of quantiles.
$p \quad$ vector of probabilities.
$\mathrm{n} \quad$ number of observations. If length $(\mathrm{n})>1$, the length is taken to be the number required.
location location parameter $\mu$, which is the mean.
scale scale parameter $\phi$. Scale must be positive.
log, log. p logical; if TRUE, probabilities $p$ are given as $\log (p)$.
lower.tail logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X>x]$.

## Details

If location or scale are not specified, they assume the default values of 0 and 1 respectively.
The Laplace distribution with location $\mu$ and scale $\phi$ has density

$$
f(x)=\frac{1}{\sqrt{2} \phi} \exp (-\sqrt{2}|x-\mu| / \phi)
$$

where $-\infty<y<\infty,-\infty<\mu<\infty$ and $\phi>0$. The mean is $\mu$ and the variance is $\phi^{2}$.
The cumulative distribution function, assumes the form

$$
F(x)= \begin{cases}\frac{1}{2} \exp (\sqrt{2}(x-\mu) / \phi) & x<\mu \\ 1-\frac{1}{2} \exp (-\sqrt{2}(x-\mu) / \phi) & x \geq \mu\end{cases}
$$

The quantile function, is given by

$$
F^{-1}(p)= \begin{cases}\mu+\frac{\phi}{\sqrt{2}} \log (2 p) & p<0.5 \\ \mu-\frac{\phi}{\sqrt{2}} \log (2(1-p)) & p \geq 0.5\end{cases}
$$

## Value

dlaplace, plaplace, and qlaplace are respectively the density, distribution function and quantile function of the Laplace distribution. rlaplace generates random deviates from the Laplace.

The length of the result is determined by n for rlaplace , and is the maximum of the lengths of the numerical parameters for the other functions.

## See Also

Distributions for other standard distributions and rmLaplace for the random generation from the multivariate Laplace distribution.

## Examples

```
x <- rlaplace(1000)
## Q-Q plot for Laplace data against true theoretical distribution:
qqplot(qlaplace(ppoints(1000)), x, main = "Laplace Q-Q plot",
    xlab = "Theoretical quantiles", ylab = "Sample quantiles")
abline(c(0,1), col = "red", lwd = 2)
```

```
mLaplace Multivariate Laplace distribution
```

## Description

These functions provide the density and random number generation from the multivariate Laplace distribution.

## Usage

dmLaplace (x, center $=\operatorname{rep}(0$, nrow(Scatter)), Scatter $=\operatorname{diag}(l e n g t h(c e n t e r)), \log =$ FALSE $)$
rmLaplace(n = 1, center $=$ rep(0, nrow(Scatter)), Scatter = diag(length(center)))

## Arguments

center a $k \times 1$ vector giving the locations.
Scatter a $k \times k$ positive-definite dispersion matrix.
log logical; if TRUE, the logarithm of the density function is returned.

X
n
vector or matrix of data. the number of samples requested.

## Details

The multivariate Laplace distribution is a multidimensional extension of the one-dimensional or univariate symmetric Laplace distribution. There are multiple forms of the multivariate Laplace distribution. Here, a particular case of the multivarite power exponential distribution introduced by Gomez et al. (1998) is considered.
The multivariate Laplace distribution with location $\boldsymbol{\mu}=$ center and $\boldsymbol{\Sigma}=$ Scatter has density

$$
f(x)=\frac{\Gamma(k / 2)}{\pi^{k / 2} \Gamma(k) 2^{k+1}}|\boldsymbol{\Sigma}|^{-1 / 2} \exp \left\{-\frac{1}{2}\left[(\boldsymbol{x}-\boldsymbol{\mu})^{T} \boldsymbol{\Sigma}^{-1}(\boldsymbol{x}-\boldsymbol{\mu})\right]^{1 / 2}\right\}
$$

The function rmLaplace is an interface to $C$ routines, which make calls to subroutines from LAPACK. The matrix decomposition is internally done using the Cholesky decomposition. If Scatter is not non-negative definite then there will be a warning message.

## Value

If $n=1$ a vector of the same length as center, otherwise a matrix of $n$ rows of random vectors.

Gomez, E., Gomez-Villegas, M.A., Marin, J.M. (1998). A multivariate generalization of the power exponential family of distributions. Communications in Statistics - Theory and Methods 27, 589600.

## Examples

```
# dispersion parameters
Scatter <- matrix(c(1,.5,.5,1), ncol = 2)
Scatter
# generate the sample
y <- rmLaplace(n = 2000, Scatter = Scatter)
# scatterplot of a random bivariate Laplace sample with center
# vector zero and scale matrix 'Scatter'
par(pty = "s")
plot(y, xlab = "", ylab = "")
title("bivariate Laplace sample", font.main = 1)
```

## Description

Simulate one or more responses from the distribution corresponding to a fitted lad object.

## Usage

```
## S3 method for class 'lad'
simulate(object, nsim = 1, seed = NULL, ...)
```

## Arguments

object an object representing a fitted model.
nsim number of response vectors to simulate. Defaults to 1.
seed an object specifying if and how the random number generator should be initialized ('seeded'). For the "lad" method, either NULL or an integer that will be used in a call to set. seed before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return . Random. seed as the "seed" attribute, see 'Value'.
... additional optional arguments.

## Value

For the "lad" method, the result is a data frame with an attribute "seed". If argument seed is NULL, the attribute is the value of . Random. seed before the simulation was started.

## Author(s)

Tymoteusz Wolodzko and Felipe Osorio

## Examples

```
fm <- lad(stack.loss ~ ., data = stackloss)
sm <- simulate(fm, nsim = 4)
```

## Description

Returns the variance-covariance matrix of the main parameters of a fitted model for lad objects. The "main" parameters of model correspond to those returned by coef, and typically do not contain a nuisance scale parameter.

## Usage

\#\# S3 method for class 'lad'
vcov(object, ...)

## Arguments

object an object representing a fitted model.
... additional arguments for method functions.

## Value

A matrix of the estimated covariances between the parameter estimates in the linear regression model. This should have row and column names corresponding to the parameter names given by the coef method.
